

Chapter 9 Motion

Mrs. Valentine
4th and 6th Periods

Section 1

Describing and Measuring Motion

- Motion is everywhere. When you walk to class, change seats, go to lunch, and play at recess, you are in motion.

- **Definition:** Motion – the distance of one object from another is changing.

- Since the distance between you and the walls of the room is not changing, you can conclude that you are not in motion.

Recognizing Motion

- However, even though you are staying in your seat, you are still in motion in other ways.
- For example, you are currently moving 30km/s. To give you an idea of how fast this is, if you were to fly a plane this quickly, you could travel from NYC to LA in about 2 minutes.

- You are moving at this rate because the Earth is spinning at this rate, and therefore everything on Earth is moving at this rate.

Recognizing Motion

- Motion can be dependent on point of view.
- For example, if you compare a book on your desk to the floor, it may not be in motion.

- Something to think about: Two people are in space, looking out the windows of their ships. The person in ship A sees the person in ship B passing them. Conversely, the person in ship B sees the person in ship A passing them. Who is moving?

Recognizing Motion

- To answer the question, you need still object to compare the ships to.
- **Definition:** Reference Point – a place or object used for comparison to determine if something is in motion.
- The reference point is assumed to be stationary.

Choosing a Reference Point

- Choosing a reference point can be tricky.
- For example, if you are riding in a car, you would want to pick a reference point that is not moving at the same approximate speed you are.
- What would be a good reference point for the car in the picture?

Describing Distance

- When describing distance, a scientist must include units.
- For example, when we measure something small, such as a pen, we use inches, cm, or mm.
- REVIEW: Scientists have standardized measurements in the scientific world. We use the International System of Units (SI Units).
- The basic SI unit for length is meter.

1.0 in, 2.54 cm, 25.4 mm

Describing Distance

- A meter is a little bit longer than a yard.
- This is where our SI conversions are really going to start coming in handy.

- Short distances, such as the length of your desk, are measured in centimeters.

- The diameter of a ring might be measured in millimeters.

Calculating Speed

- Speed depends on two things:
 1. The distance the object moves.
 2. How long it takes for the object to move.
- **Definition:** Speed (s or c) – the distance an object travels in one unit of time

7m

Think of speed as how fast an object is moving.

- This is a type of rate.

Calculating Speed

- To calculate the speed of an object, divide the distance it has traveled in the amount of time it traveled in.

$$s = \frac{d}{t}$$

- The SI units for speed are meters per second (m/s).

7m

If this runner is moving 7 meters in 2 seconds, she is moving at a speed of 3.5m/s.

Constant Speed

- If the speed of an object does not change, it is said to have constant speed.

- If the object has constant speed, and you know how far it went, you can calculate how long it took.

Constant Speed Practice Problems

(p. 1 in packet)

$$s = \frac{d}{t}$$

- If Jenny is moving with a constant speed of 21 m/s, how long did it take her to travel 17.5 meters?

$$s = 21\text{m/s}$$

$$d = 17.5\text{ m}$$

$$21\text{ m/s} = \frac{17.5\text{m}}{t}$$

$$t = 0.83\text{ seconds}$$

- If John is moving with a constant speed of 2 mi/hr, how far was he able to walk in 1.75 hours?

$$s = 2\text{mi/hr}$$

$$t = 1.75\text{ hr}$$

$$2\text{ mi/hr} = \frac{d}{1.75\text{ hr}}$$

$$d = 3.5\text{ miles}$$

Constant Speed Practice Problem

(p. 1 in packet)

$$s = \frac{d}{t}$$

- If Jonah traveled at 30 km/hr for 0.5 hours and at 21.3 km/hr for 1.2 hours, how far did he travel?

$$s = 30\text{km/hr}$$

$$t = 0.5\text{ hr}$$

$$30\text{ km/hr} = \frac{d}{0.5\text{hr}}$$

$$(30\text{km/hr}) (0.5\text{hr}) = d$$

$$15\text{ km} = d$$

$$s = 21.3\text{km/hr}$$

$$t = 1.2\text{ hr}$$

$$21.3\text{ km/hr} = \frac{d}{1.2\text{hr}}$$

$$(21.3\text{km/hr}) (1.2\text{hr}) = d$$

$$25.56\text{ km} = d$$

$$15\text{ km} + 25.56\text{ km} = d$$

$$40.56\text{ km} = d_{\text{total}}$$

Average Speed

- Most objects do not move at constant speed.

- If an object does not have a constant speed, the average speed can be determined.
- This is done by dividing the total distance by the total time.

$$S_{\text{average}} = \frac{d_{\text{total}}}{t_{\text{total}}}$$

Average Speed Practice Problem

(p.2 in packet)

- If Jonah traveled **15 miles** during his first **half hour** of travel, and **25.56 miles** during **1.2 hours** of travel, what is his average speed?

$$15 \text{ miles} + 25.56 \text{ miles} = d_{\text{total}}$$

$$40.56 \text{ miles} = d_{\text{total}}$$

$$0.5 \text{ hours} + 1.2 \text{ hours} = t_{\text{total}}$$

$$1.7 \text{ hours} = t_{\text{total}}$$

$$S_{\text{average}} = \frac{40.56 \text{ miles}}{1.7 \text{ hours}}$$

$$S_{\text{average}} = 23.86 \text{ mi/hr}$$

Average Speed Practice Problems

(p.2 in packet)

- If Dorothea walked 1.5 miles during her first half hour of travel, and 4.2 miles during 1.25 hours of travel, what is her average speed?

$$S_{\text{average}} = 3.25 \text{ mi/hr}$$

- If Henry traveled 34.51 miles during his first forty-five minutes of travel, and 113.5 miles during 1.8 hours of travel, what is his average speed?

$$S_{\text{average}} = 58.04 \text{ mi/hr}$$

Describing Velocity

- The speed of an object does not tell you the direction of the object's motion.
- **When you know both the speed and direction of an object's motion, you know the velocity of the object.**
- **Definition:** Velocity (v) – Speed in a given direction.
- When velocity is reported, the direction must be included.
- Velocity is typically reported rather than speed as both speed and direction are important pieces of information to have.

Active Demonstration

- Let the races begin!
- We will be going outside to judge speed and velocity.
- Materials Needed: 2 ropes, 2 blindfolds, 1 timer, 1 tape measure.
- Everyone must run at least one race.
- Which was more challenging: when you were able to determine your direction or not?

Graphing Motion

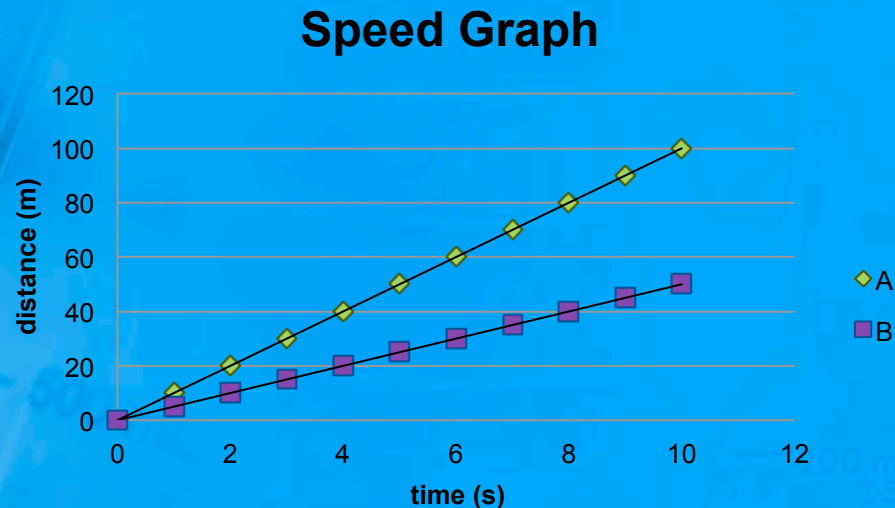

- You can show the motion of an object on a line graph in which you plot distance against time.

- Time** will be on the x-axis and **distance** will be on the y-axis.
- A point on the graph (x,y) will represent the location of an object at a given time.

Graphing Motion

- **Definition:** Slope (m) – the steepness, or slant, of a line on a graph.

A has a larger slope than B because it is a steeper line.

- The slope of the line of the graph will tell you how fast one variable changes in relation to the other.
- Therefore, we can use the slope of the line of a graph depicting motion to determine the speed of the object.

Graphing Motion

- Let's read the Exploring: Motion Graphs on page 290.
- The first graph shows that the jogger traveled 170m each minute. Therefore, the average speed between any two points is 170m/min.
- Copy the graph and extend the line.

Exploring: Motion Graphs

(p. 2 in packet)

- On the second graph, what happened during the sixth through eighth minutes? The jogger stopped.
- What effect did the stop have on the jogger's average speed? Average speed was lowered. New Avg. Spd.: 119m/min
- What was the difference in the jogger's average speed between the first and the second day? 51m/min.
- Let's look at the third graph. Compare the slope of the third to the first. The slope of the first graph is greater.
- How fast would the jogger be running if the graph was flat? 0m/min.

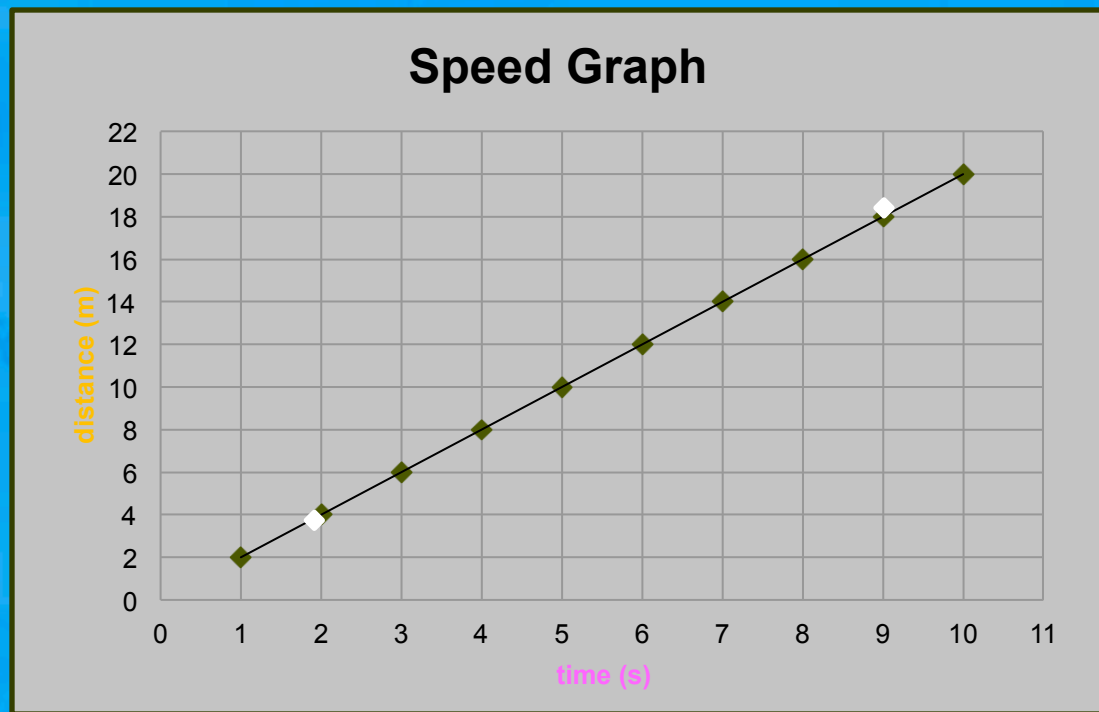

Calculating Slope

- The slope of a line is its rise divided by its run. $m = \frac{\text{rise}}{\text{run}}$
- Therefore, in order to calculate the slope of a line, two points on the line must be known.
- Typically, it is preferred that these points not be directly beside one another. This is to ensure that the slope is more accurate.
- The rise is the vertical distance between the two points. The run is the horizontal distance between the two points.

$$m = \frac{y_2 - y_1}{x_2 - x_1}$$

Calculating Slope

- Let's calculate the slope of the following line.

- We can choose the points $(2, 4)$ and $(9, 18)$ to calculate the slope.

Calculating Slope

$$m = \frac{\text{rise}}{\text{run}}$$

NOTE: We subtracted the first from the second in both cases. It does not matter which order you do it in, so long as it is the same both times.

[Points (2,4) and (9,18)]

- Remember that the rise is the vertical difference. Therefore, we must subtract the y values.

$$18m - 4m = 14m$$

- The run is the horizontal difference. Therefore, we must subtract the x values.

$$9s - 2s = 7s$$

- We then can divide the rise by the run in order to determine slope.

$$m = \frac{14m}{7s} = 2m/s$$

- Using the other equation, these steps can be done all at once.

$$m = \frac{y_2 - y_1}{x_2 - x_1} \quad m = \frac{18 - 4}{9 - 2} = \frac{14m}{7s} = 2m/s$$

Slope Practice Problem

(p. 3 in packet)

- Determine the slope of the speed graph below.

Speed Graph

$m = 6\text{m/s}$

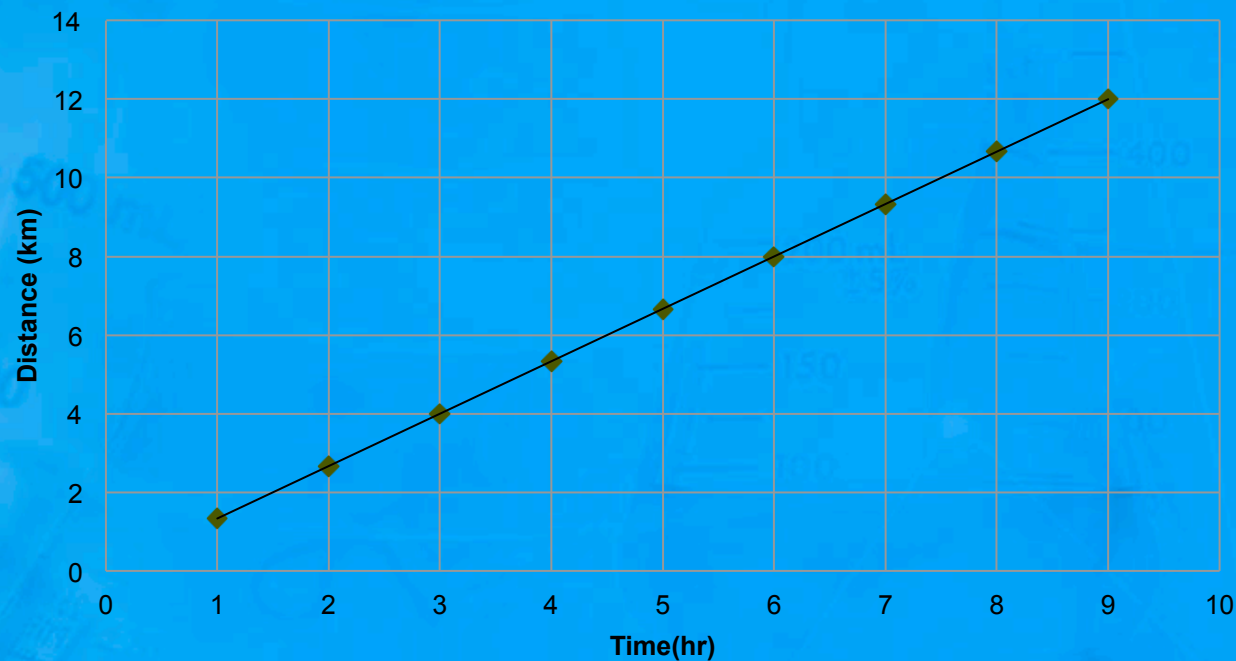

Line Equations

- Once we have the slope, we can use it to determine the equation of the line.
- The equation of a line is $y=mx+b$ where m is the slope and b is the y -intercept.
- In this case, and in the case of all speed graphs, you haven't moved before you start counting time.
- Therefore, the y -intercept is typically $(0,0)$, making the equation for speed graph lines $y=mx$.
- The equation of our line, therefore, is $y=2x$

Line Equation Practice Problem (p. 3 of packet)

- Determine the equation of the line in the graph below.

Speed Graph

$$y = 1.33x$$

Different Slopes

- Note that when an object in motion changes its speed, the slope of the line of the graph representing it changes.
- Let's look at Figure 8 on page 293.
- Each different slope can be seen as a different segment of the same graph, and would have to be calculated separately.
- A horizontal line represents an object that is not in motion, since there is no change in distance.

Section 2

Slow Motion on Planet Earth

- Let's have a look at a world map.

- Notice how the land masses look like a giant puzzle.

What are Earth's Plates?

- The upper layer of Earth consists of more than a dozen major pieces called plates.

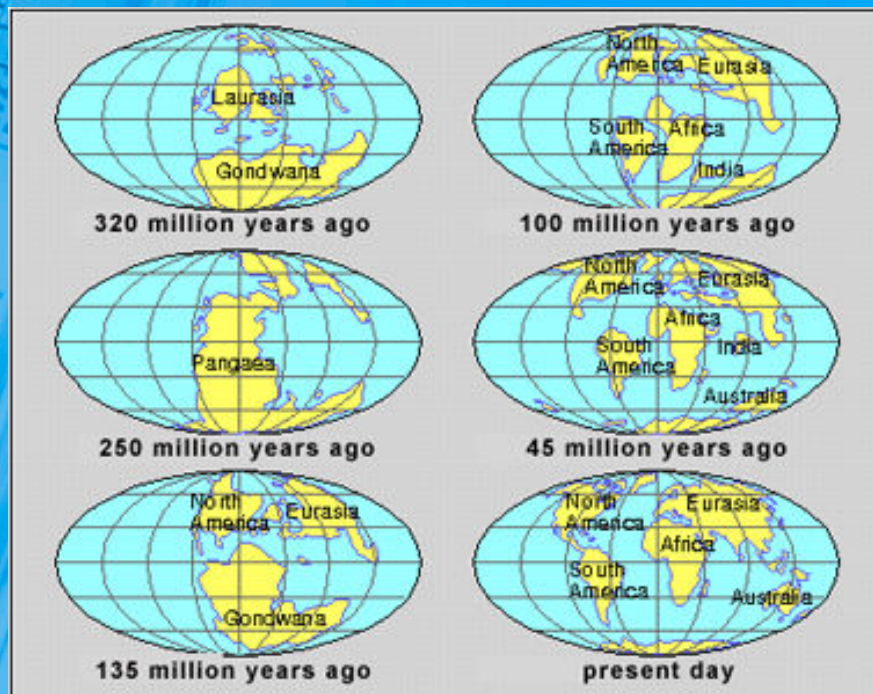

- **According to scientists explanations, known as the theory of plate tectonics, Earth's plates move ever so slowly in various directions.**

- Some plates will pull away from one another while other plates will come together.

How Fast Do Plates Move?

- Some small plates move as fast as several centimeters per year, while others move only a couple of millimeters per year.
- Let's look at Figure 10 on page 298.

Knowing how fast the plates are moving will allow for scientists to make predictions on what the earth will look like after a set period of time.

Calculating Distance Practice Problem

(p. 4 in packet)

- Suppose a plate moves 5 centimeters over the course of a year. It can be said to have a speed of 5cm/yr.
- Try using this speed to determine how far the plate will have moved in 1000 years.

$$s = 5\text{cm/yr}$$

$$t = 1000 \text{ yr}$$

$$s = \frac{d}{t}$$

$$5\text{cm/yr} = \frac{d}{1000 \text{ yr}}$$

$$(5\text{cm/yr}) (1000\text{yr}) = d$$

$$d = 5000\text{cm} = 50\text{m}$$

Sharpen Your Skills (pg 297)

(p. 4 in packet)

- LA is on the Pacific plate moving NW. San Francisco is on the North American plate moving SE.
- These cities are moving toward each other at 5cm/yr. If the cities are 554,000m apart, how long will it take for them to reach each other?
- Use the map to the left to locate LA and San Francisco. Where do you think the plate runs?

Demonstration

- Measure the length of your step (back toes to front heel) in inches.
- Convert this distance to cm. Recall that $1\text{in} = 2.54\text{cm}$.
- Imagine that you walk 10000 steps in one day on average.
- What is your average speed? Convert this to cm/yr and compare to the average speed of a fast plate.

Section 3

Acceleration

- It is rare for any motion to stay the same for a long time.
- Changes in motion can be described in much the same way that speed and velocity have been described.
- Example – A car, which has been stopped at a red light, gets a green light and begins to move. If the car is in a 35mi/hr zone, when the gas pedal is pushed, does the car instantly go at 35mi/hr?

Acceleration in Science

- The answer to this question is no. The car must accelerate first.
- In everyday language, acceleration means “speeding up.”
- In science, acceleration has a slightly more specific definition.
- **Definition:** Acceleration (α) – the rate at which velocity changes.

Acceleration

- Remember, velocity has two components: both speed and direction.
- **In science, acceleration refers to increasing speed, decreasing speed, or changing direction.**

- Brief demonstration. Materials – ball on string. How is the ball accelerating?

Increasing Speed

- At any time the speed of an object increases, it is accelerating.
- Examples include:
 1. Throwing a ball
 2. Launching a rocket
 3. Speeding up a car
- People can experience this kind of acceleration as well. When we start running or skating, we accelerate up to the speed we want to be going.

Decreasing Speed

- Decreasing speed is another form of acceleration.
- This process is often referred to as deceleration.
- Examples include:
 1. Stopping a car
 2. A runner slowing to a walk
 3. A ball being caught

• True or False:

- When you step on the gas while driving, you are accelerating.
- When you step on the brake, you are accelerating.

Changing Direction

- Acceleration can occur even when speed is constant.
- This happens if the object changes direction.
- Examples include:

Changing Direction

- Many objects are constantly changing direction without changing speed.
- The simplest form of this kind of acceleration is known as circular motion.
- Examples include:

- Demonstration: Proving that circular motion has a change in direction. Materials: CD, Arrow, Tape, Marker

Velocity and Acceleration

Calculating Acceleration

- To determine the acceleration of an object, you must calculate the change in velocity during each unit of time.

- This can be summarized in the following equation:

$$a = \frac{V_f - V_i}{t}$$

- If velocity is measured in m/s and time is measured in s, then what is acceleration measured in?

$$m/s/s = m/s^2$$

- If the object's speed changes by the same amount during each unit of time, the acceleration is the same.
- If the acceleration varies, the average acceleration can be described.

Calculating Acceleration Practice Problem (p. 5 in packet)

- A car advertisement states that a certain car can accelerate from **rest** to **90km/hr** in **9 seconds**. Find the car's acceleration in mi/hr^2 .

$$v_f = 90\text{km/hr}$$

$$v_i = 0\text{km/hr}$$

$$t = 9\text{s} = 0.0025\text{hr}$$

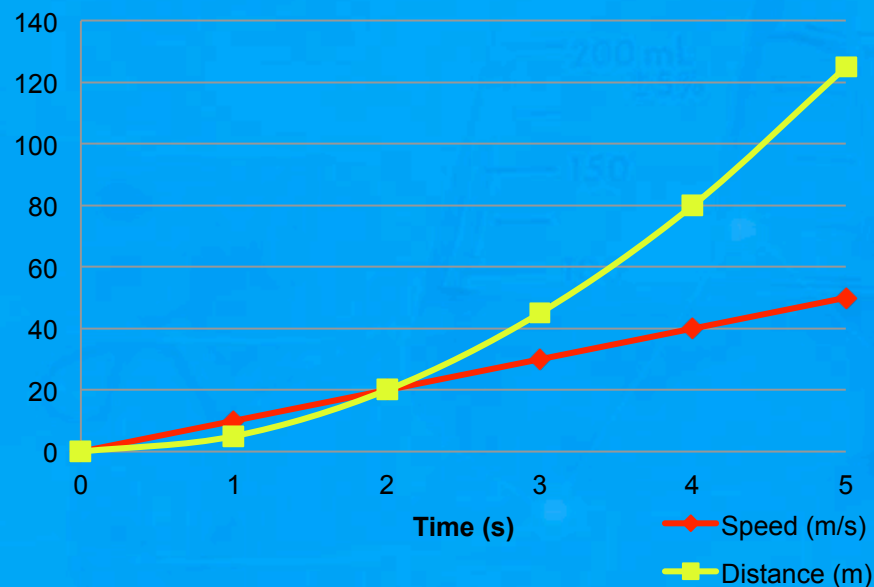

$$9\text{s} \times \frac{1\text{min}}{60\text{s}} \times \frac{1\text{hr}}{60\text{min}} = 0.0025\text{hr}$$

$$a = \frac{90\text{km/hr} - 0\text{km/hr}}{0.0025\text{hr}}$$

$$= 36000\text{km/hr}^2$$

Graphing Acceleration

- If one graphs speed versus time for constant acceleration, the line will be linear.
- If one graphs distance versus time for constant acceleration, the graph will be nonlinear.
